[003 / ARCHITECTURE]

Integration foundation

Disconnected tools become a stable integration layer that can support future automations.

CLIENT	SECTOR	DURATION	STACK
Representative systems team	Multi-tool operations	10 weeks	APIs - Sync jobs - Monitoring

[01] Problem

- Important data lived across disconnected tools, creating duplicate entry, brittle reports, and unclear ownership.
- Teams relied on manual exports and imports to keep systems aligned.
- Automation was risky because source-of-truth rules were not documented.

[02] Approach

- Defined integration boundaries and ownership before connecting systems.
- Established source-of-truth rules, sync direction, retry behavior, and monitoring points.
- Kept the first release focused on stable data movement rather than broad automation.

[03] Implementation

01 **System inventory**

Mapped source systems, ownership, data quality issues, and integration boundaries.

02 **Contract design**

Defined API contracts, sync rules, retry behavior, and monitoring expectations.

03 **Automation-ready layer**

Prepared the foundation for dashboards, workflow apps, and AI-assisted processes.

[04] Results

	DUPLICATE ENTRY	INTEGRATION OWNERSHIP	AUTOMATION READINESS
BEFORE	3 systems	Unclear	Brittle
AFTER	1 source	Defined	Stable

> "The biggest win was not another integration. It was finally agreeing where the business logic belongs."

NEXT STEP

Use this format to scope a practical automation or software roadmap.
